Abstract

(小四号加粗, Times New Roman, 段前 1 行、段后 0.5 行间距)

Investigations of the influence of GM soya on the birthrate and survival of the offspring of Wistar rats were performed. A group of female rats were fed with GM soya flour before mating and pregnancy. The control group of females were fed with traditional soya and the third group of females, the positive control group, received feed without any soya. The weight and the mortality rate of the newborn pups were analyzed. The study showed that there was a very high rate of pup mortality (55.6%) in the GM soya group in comparison with the control group and the positive control group (9% and 6.8% respectively). Moreover, death in the first group continued during lactation, and the weights of the survivors were lower than those from the other two groups. It was revealed in these experiments that GM soya could have a negative influence on the offspring of Wistar rats. (五号)

Garbage is now becoming a serious challenge to the city's future development (Cai, 2013) and detrimental to people's health (Cai, 2013). Since garbage is a scarce resource (Peng, 2011), recycling has received much attention as an effective garbage management method (Wen et al., 2008; Wang et al., 2009). Recycling heavily relies on garbage classification. Numerous studies have been dedicated to the efficient garbage classification (Zhang, 2007; Chen et al., 2013; Fukuyama, 2000). The study of residents' attitudes and participation which play a vital role in garbage classification. Chen et al. (2013) and Fukuyama (2000) reported that the noncooperation of residents might lead to the failure of garbage classification. Regarding the efficient garbage classification involve the government's regulation of incentive systems (punishment and subsidy) (Fukuyama, 2000), the publicity of the regulation. For example, studies found that New South Wales specialized companies for garbage management (Peng, 2011). Japan issued the Act as early as in 1970 (Wang et al., 2009). In the U.S., garbage classification is the Resource Conservation and Recovery Act (RCRA) (Wen et al., 2008).

Materials and Methods

Participants

A standard questionnaire was mailed to a randomly selected sample of 2,000 persons in May, 2015, which was responded by 300 (15%) persons. Among the respondents, 290 (96.67%) were aged 17-24. Males accounted for 43.33% and females 56.67%. Interviews were also conducted among residents in some residential estates near Fudan University, the estates where the regulation was being trialed. They were aged 59 to 74, and all female. Participants were asked open-ended questions about the knowledge, incentives and attitudes toward garbage classification. Information provided by sanitation workers and employees at garbage management stations was also collected.

Procedure

The questionnaire designed for anonymous response is comprised of 11 questions, which can be divided into five parts with regard to their purposes:

Q1 and Q2 gauged the general public's awareness of garbage classification. Q1 investigated their knowledge of classified garbage bins, while Q2 attempted to measure the publicity of garbage classification. Residents' knowledge and habit of classifying domestic garbage was investigated in
